Abstract

Gracilariopsis grevogerungii G.H.Boo & I.K.Hwang, **sp. nov.**, a new species from southern Indonesia, is described based on morphological features and molecular data from two genes: the plastid-encoded *rbcL* and the mitochondrial COI-5P. *Gracilariopsis grevogerungii* can be distinguished from other species in the same genus by a combination of traits: terete main axes with irregular branches and scarce short branchlets, and hemispherical cystocarps with up to 3 ostioles and 9–14 cell-layered pericarp. The species occurred on sandy-muddy substrates in the intertidal to the shallow subtidal zone. Phylogenies based on *rbcL* and COI-5P revealed its sister relationship with the subclade of *Gp. heteroclada* from China and *Gp. mclachlanii* from Tanzania. Our results highlight the need for further findings of the agar-yielding Gracilariaeae in southern Indonesia, expanding our knowledge of red algal diversity in tropical Southeast Asia.

Key words: Agar-yielding, Gracilariaeae, molecular marker, morphology, Southeast Asia

Gracilariopsis E.Y.Dawson (Gracilariaeae) is generally known as one of the major sources of agar used in food, healthcare and biotechnology industries. *Gracilariopsis* was established by Dawson (1949) to accommodate species that were previously placed in *Gracilaria* Greville and presented a small-celled, broad-based gonimoblast and the absence of nutritive filaments connecting gonimoblast with the pericarp. The established type species for the genus was *Gp. sjoestedtii* (Kylin) E.Y.Dawson. However, Papenfuss (1967) merged *Gracilariopsis* into *Gracilaria* because of the lack of morphological difference at the genus level based on observations of *Gp. sjoestedtii* and *Gracilaria verrucosa* (Hudson) Papenfuss, the generitype of *Gracilaria*. Ohmi (1958) reinstated *Gracilariopsis* based on the observation of *Gp. chorda* (Holmes) Ohmi from Japan, whereas Yamamoto (1978) included it within *Gracilaria*, despite his beautiful illustrations showing the superficial formation of spermatangia and the absence of nutritive tubular filaments in cystocarps. Fredericq and Hommersand (1989) reinstated *Gracilariopsis* including four species which have superficial spermatangia and lack nutritive tubular cells. *Gracilariopsis lemeneiformis* (Bory) Dawson, Acleto & Foldvik was designated as the generitype because of its priority over *Gp. sjoestedtii*.

Gracilariopsis has been robustly supported in phylogenies based on nuclear small subunit ribosomal DNA (SSU rDNA) and plastid *rbcL* gene sequence (Bird et al. 1994; Gurgel et al. 2003a, b). Gurgel et al. (2003b) designated the generitype of *Gracilariopsis* as *Gp. andersonii* (Grunow) Dawson, based on material from the northwest coast of America. The authors confirmed that *Gp. lemeneiformis*, for a long time considered a widespread species, is likely restricted to the Peruvian coast, and the collections of *Gp. lemeneiformis* from northwestern America correspond to *Gp. andersonii*. They also indicated that the collections of *Gp. lemeneiformis* from China and Japan may represent an undescribed species that is related to *Gp. heteroclada* J.-F.Zhang & B.-M.Xia.

The knowledge on species diversity of *Gracilariopsis* has improved with the increase of sequences availability, especially COI-5P and *rbcL* data from various regions (Bellorin et al. 2008; Gurgel et al. 2003a, b; Iyer et al. 2005; Le and Lin 2006; Lin 2008; Muangmai et al. 2014; Suzuki and Terada 2022). Recently, phylogenetic relationships of species within *Gracilariopsis* were further investigated using organellar genomes (Iha et al. 2018; Lyra et al. 2021). To date, a total of 23 species have been listed in the AlgaeBase (Guiry and Guiry 2025). Because most species of *Gracilariopsis* lack distinctive vegetative and reproductive characteristics that allow for reliable differentiation from other species (Bellorin et al. 2008), DNA sequence data is needed to evaluate the species diversity of *Gracilariopsis*.

Weber-van Bosse (1928) reported *Gracilariopsis lemeneiformis* as *Gracilaria lemeneiformis* (Bory) Greville in Indonesia, but it has not been collected since (Meinita et al. 2021). The objectives of this study were to assess the occurrence of *Gracilariopsis* species in southern Indonesia and to elucidate the taxonomic identities of the species present. During collection trips in southern Indonesia, several *Gracilariopsis*-like plants were collected from Nusa Lembongan Island, Bali. Based on detailed morphological comparisons and analyses of plastid *rbcL* and mitochondrial COI-5P sequences, we recognize these specimens as representing a new species of *Gracilariopsis*.

Materials and methods

Specimens were collected in June 2017 at Tamarind Beach ($8^{\circ}40'47.51"S$, $115^{\circ}26'10.20"E$), Nusa Lembongan Island, Bali, Indonesia (Table 1). Specimens were mounted on herbarium sheets and tissue samples were dehydrated in

| PKNU00676 (isotype) | Tamarind Beach, Nusa Lembongan Island, Bali, Indonesia; $8^{\circ}40'47.51"S$, $115^{\circ}26'10.20"E$; 21.vi.2017 | PV424436 | – |

silica gels for DNA sequencing. For anatomical observation, plants were sectioned using razor blades and were stained with 1% aqueous aniline blue. Photographs were taken with a DP-71 camera (Olympus, Tokyo, Japan) mounted on a BX-51 microscope (Olympus). Vouch specimens are housed at the Herbarium of the Department of Marine Biology, Pukyong National University, Busan, Korea (**PKNU**).

DNA extraction, polymerase chain reaction amplification, and sequencing procedures followed Boo et al. (2016). The primer set used for amplifying and sequencing was F145, F754, R898, and R1442 for plastid *rbcL* (Kim et al. 2010), and GazF1 and GazR1 for mitochondrial COI-5P (Saunders 2005). All sequences were aligned together with publicly available sequences of *Gracilariopsis* species in GenBank, using the MUSCLE algorithm in MEGA7 (Kumar et al. 2016) with default parameters and the alignment was manually adjusted. *Curdiea racovitzae* Hariot, *Gracilaria vermiculophylla* (Ohmi) Papenfuss, and *Melanthalia obtusata* (Labillardiere) J.Agardh were used as outgroups based on previous studies of the Gracilariaeae (Gurgel and Fredericq 2004; Bellorin et al. 2008; Iha et al. 2018). Sequences generated in the present study were deposited in GenBank (PV106179–PV106182, PV424435, PV424436).

Phylogenies of both datasets were reconstructed using maximum likelihood (ML) and Bayesian inference (BI). The ML analysis was performed using the W-IQ-tree webserver (Trifinopoulos et al. 2016) with 1,000 ultrafast bootstrap (BS) replications (-bb 1000) and model test option (-m TEST). The BI analysis was performed with MrBayes v.3.2.1 (Ronquist et al. 2012) using the Metropolis-coupled Markov Chain Monte Carlo (MC3) with the best-fitting substitution model selected by IQ-tree. Four million generations of two independent runs were performed with four chains and sampling trees every 100 generations. The burn-in period was identified graphically by tracking the likelihoods at each generation to determine whether they reached a plateau. Twenty-five percent of saved trees were removed, and the remaining trees were used to infer Bayesian posterior probabilities (BPP).

Results

Molecular phylogeny

Six sequences were generated in the present study, two *rbcL* and four COI-5P sequences. A total of 25 *rbcL* sequences were aligned, including 23 publicly available sequences of *Gracilariopsis* and three outgroups. In the *rbcL* phylogeny (Fig. 1), the Indonesian taxon was distinct from the other species in the genus, and formed a sister relationship with the clade of *Gp. heteroclada*, *Gp. irregularis* (I.A.Abbott) N.Muangmai, A.Chirapart & A.Lewmanomont, and *Gp. mclachlanii* Buriyo, Bellorin & M.C.Oliveira (98% MLBS, 1.0 BPP). The pairwise divergence of *rbcL* sequences between the Indonesian taxon and related species was 2.6–3.3%, with identical sequences among the Indonesian specimens.

In the COI-5P phylogeny (Fig. 2), the Indonesian taxon placed in a position largely congruent with that in the *rbcL* phylogeny, forming a clade with *Gp. heteroclada* and *Gp. mclachlanii* (100% MLBS, 1.0 BPP). The pairwise divergence of COI-5P sequences between the Indonesian taxon and related species was 4.7–6.1%, with identical sequences among the Indonesian specimens.

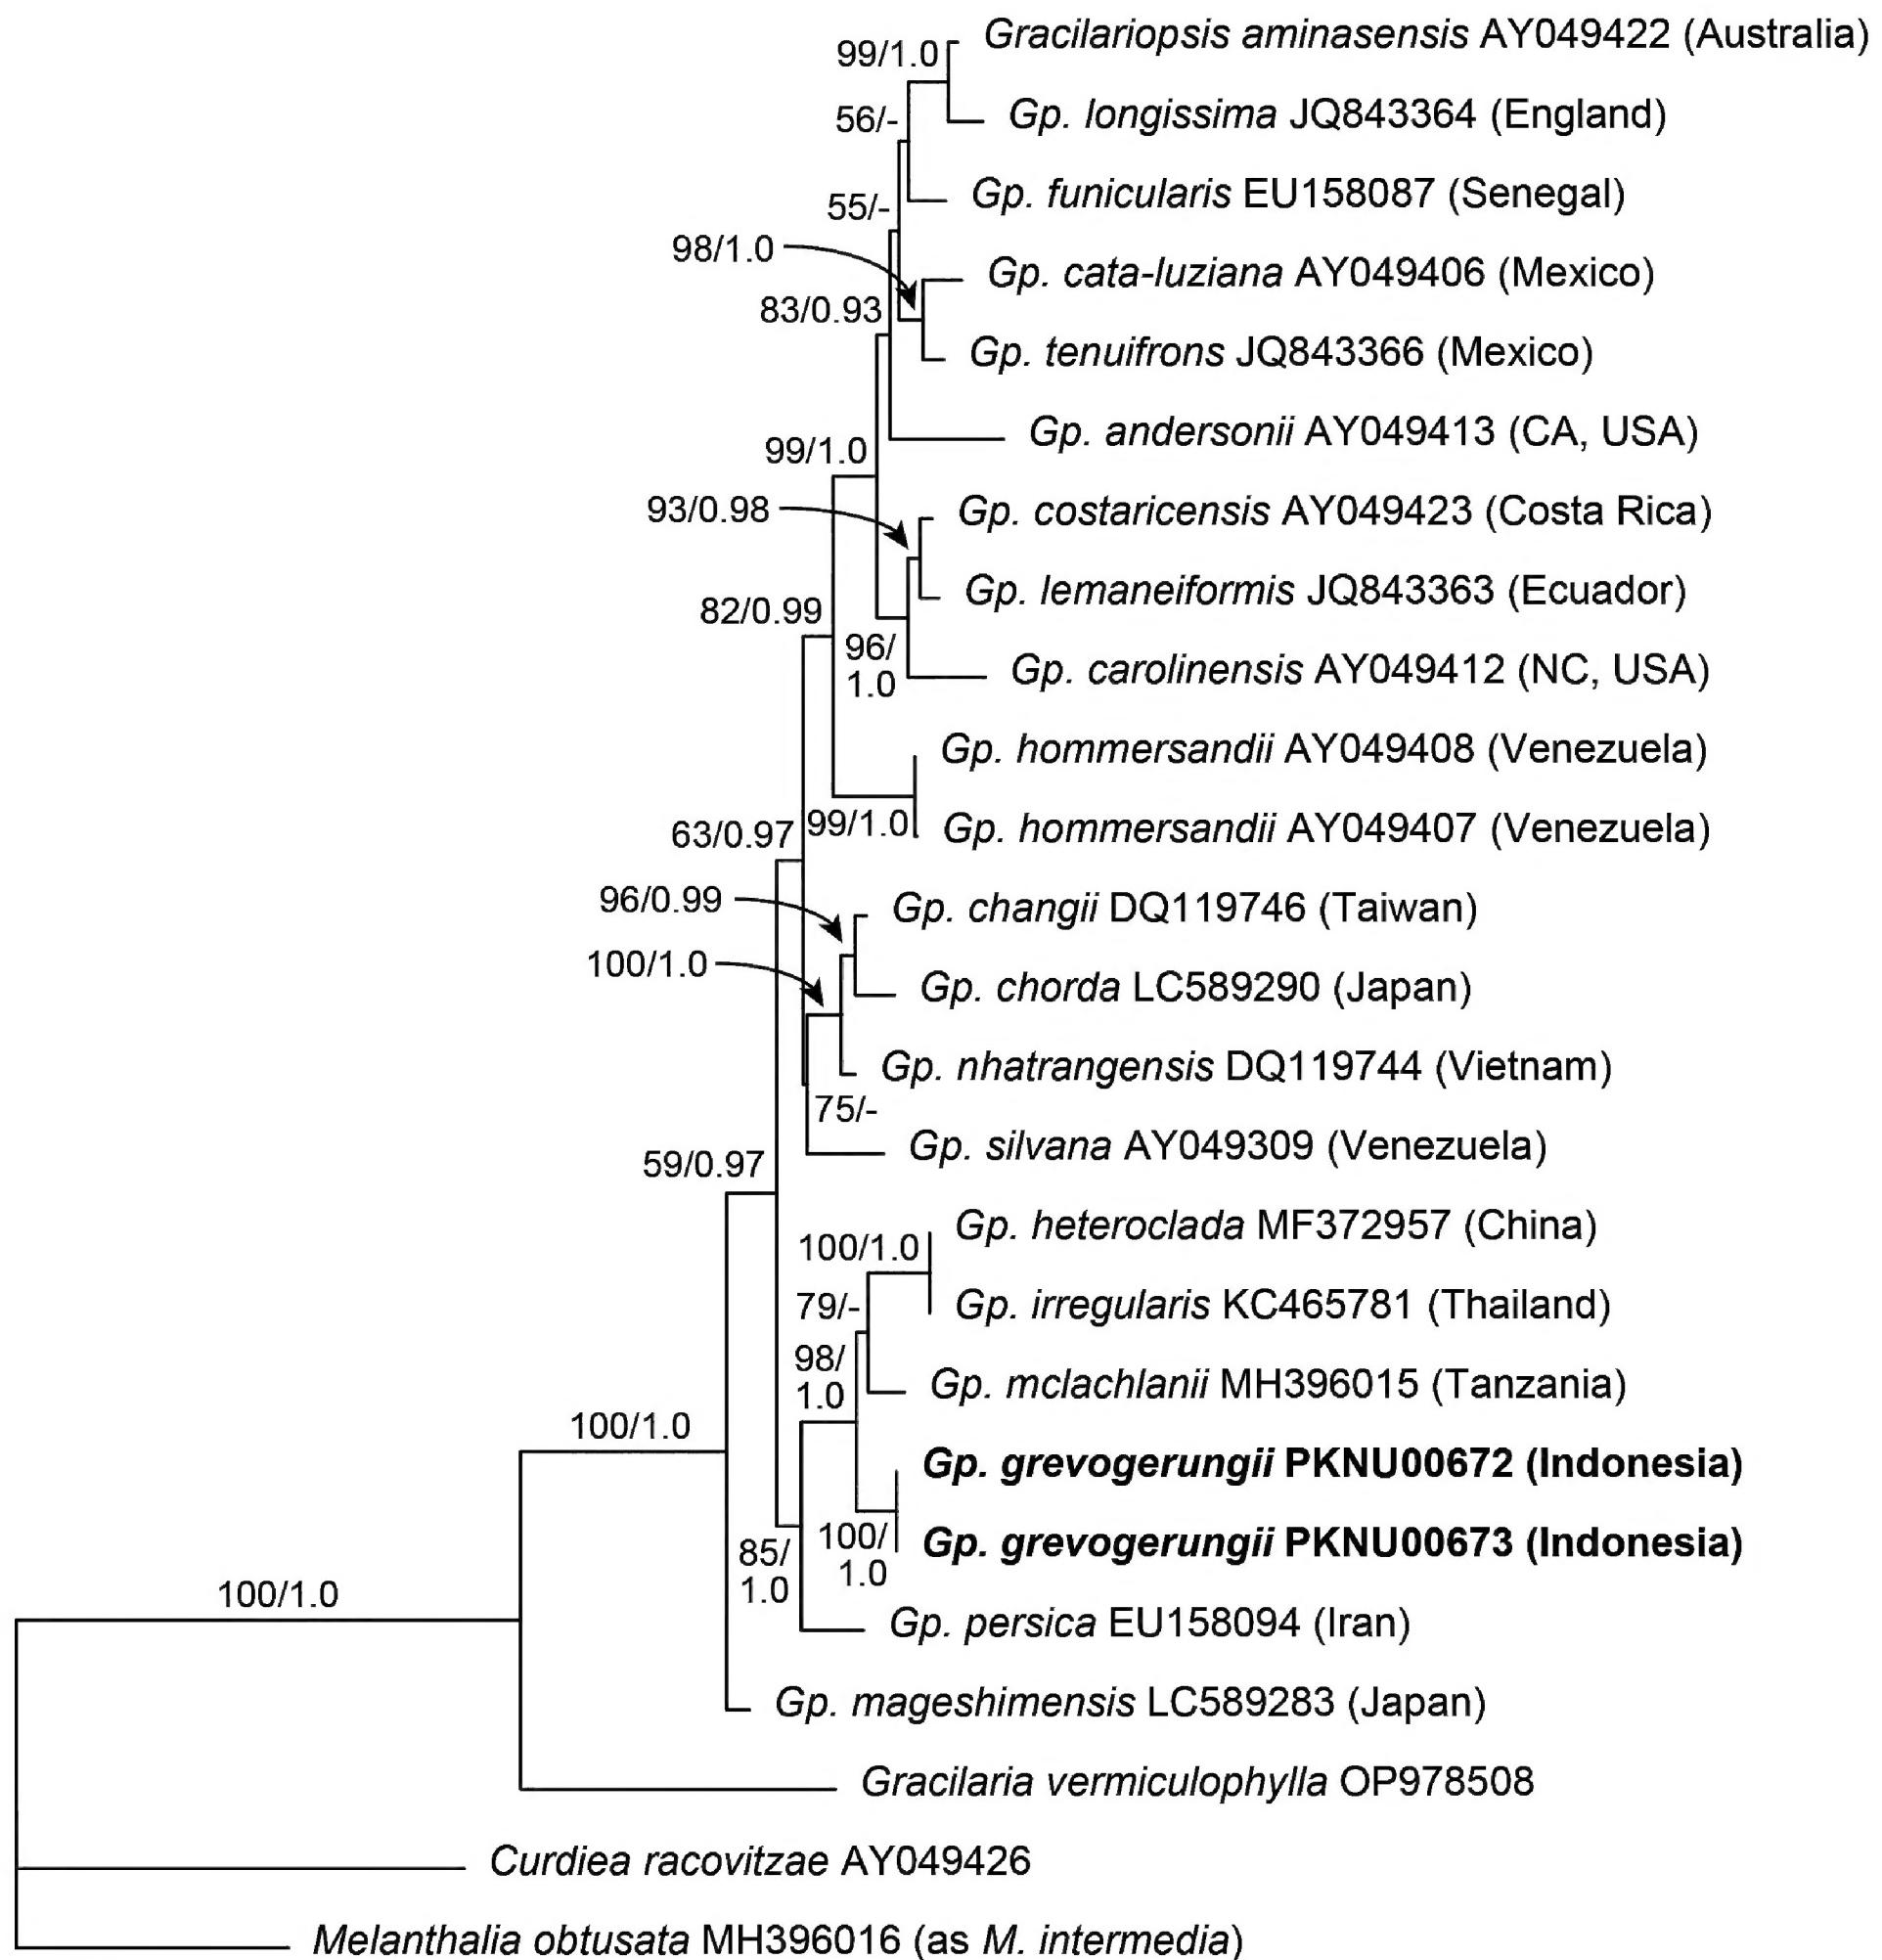

Figure 1. Maximum likelihood (ML) phylogeny of *Gracilariopsis* using plastid *rbcL* sequences. ML bootstrap values ($\geq 50\%$) and Bayesian posterior probabilities (≥ 0.9) are shown at branches. Bold letters indicate *Gp. grevogerungii* sp. nov.

Morphological observations

Details of morphological features are introduced in description and illustration below (Figs 3, 4). The *Gracilariopsis* species from Indonesia is characteristic of the genus in the absence of nutritive tubular cells between the gonimoblast and pericarp. The species can be distinguished from other species of *Gracilariopsis* by a combination of terete main axes with irregular branches with sparse, filiform branchlets (up to 4 mm), scattered tetrasporangia on axes and branches, and hemispherical cystocarps with up to 3 ostioles and 9–14 cell-layered

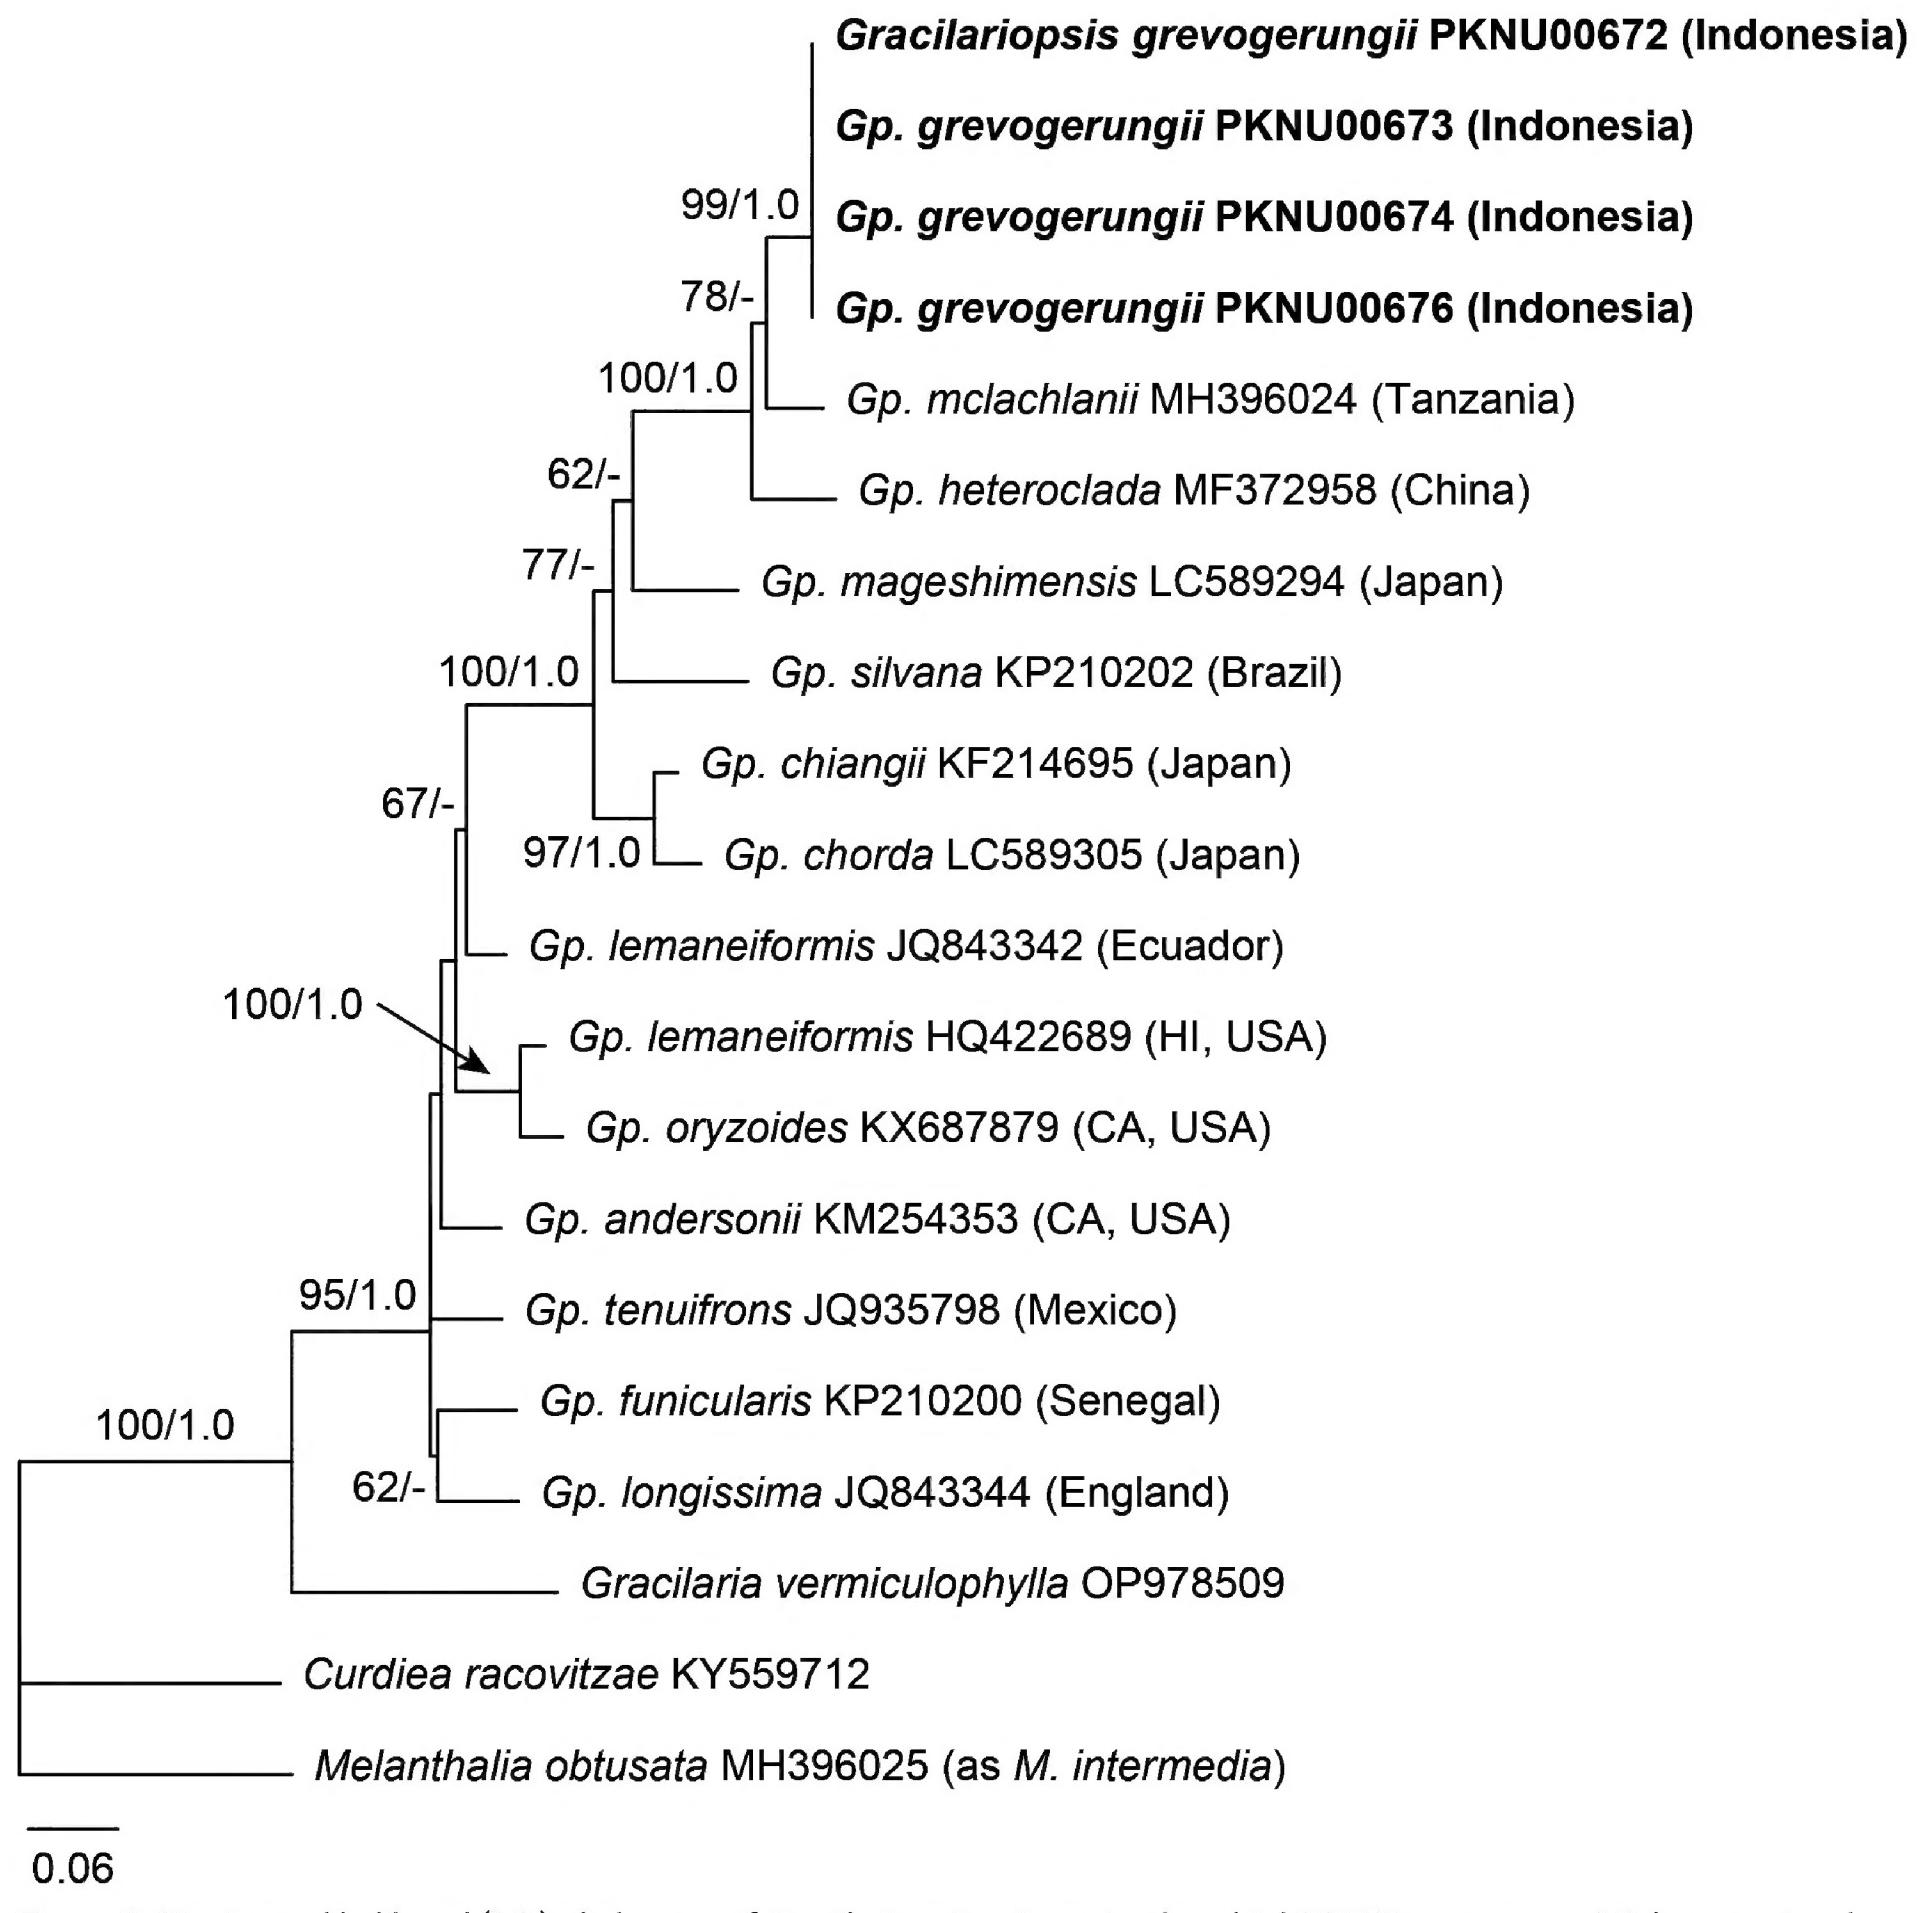

Figure 2. Maximum likelihood (ML) phylogeny of *Gracilariopsis* using mitochondrial COI-5P sequences. ML bootstrap values ($\geq 50\%$) and Bayesian posterior probabilities (≥ 0.9) are shown at branches. Bold letters indicate *Gp. revogerungii* sp. nov.

pericarps. A morphological comparison of Indonesian *Gracilariopsis* with other terete species of the genus is given in Table 2. However, without DNA sequences, it is difficult to recognize the Indonesian *Gracilariopsis*.

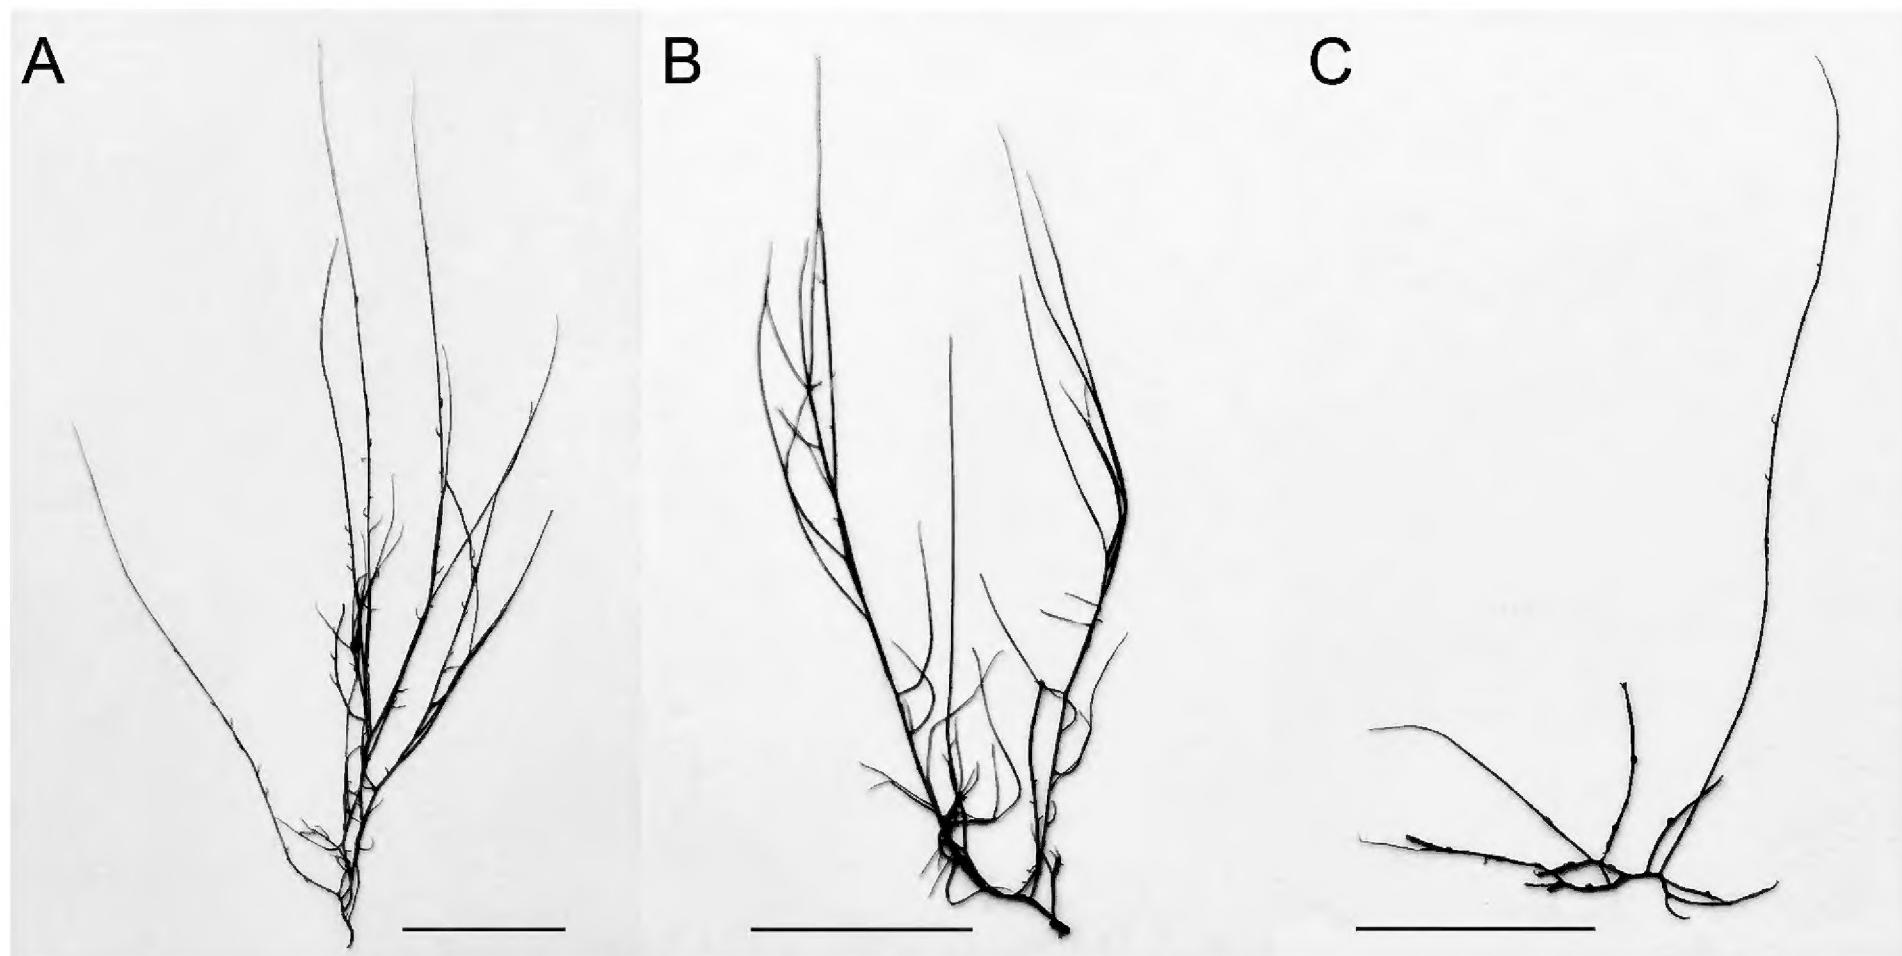

Figure 3. A–C. Habit of *Gracilariopsis grevogerungii* sp. nov. **A.** Holotype specimen (PKNU00673) from Tamarind Beach, Nusa Lembongan Island, Bali, Indonesia; 21 June, 2017; **B.** Isotype specimen having tetrasporangia (PKNU00676); **C.** Isotype specimen bearing cystocarps (PKNU00672). Scale bars: 2 cm (A–C).

the base and tapering gradually toward apices. Determinate branches up to 4 mm long, irregularly alternate or scattered. Cortices composed of two to three layers of small isodiametric or anticlinally elongate cells (Fig. 4A, B), measuring $3.2\text{--}6.4 \times 7.5\text{--}12.8 \mu\text{m}$ in size, with dense content, heavily pigmented, connected only with their parental cells by primary pit connections. Medulla composed of large globose cells, $114\text{--}163 \mu\text{m}$ in diameter in transverse sections, thick-walled and highly vacuolated, lacking pigments. Transition in cell size from cortex to medulla abrupt (Fig. 4C). Large basal cells of deciduous hairs frequently occurring near the surface. Cystocarps $492\text{--}805 \mu\text{m}$ in diameter and $689\text{--}884 \mu\text{m}$ in height, hemispherical, scattered on main axes or determinate branches, slightly constricted at the base. Cystocarps slightly constricted at the base, with up to three ostioles (Fig. 4D, E). Carposporangia initials formed in long chains and radially elongated (Fig. 4F, G). Two gonimoblasts formed in a single cystocarp (Fig. 4H). Mature cystocarps released carpospores through ostioles (Fig. 4I). Pericarps about $115 \mu\text{m}$ thick, formed by 9–14 cell layers. Tetrasporangia embedded in the cortex (Fig. 4J). Tetrasporangial initials formed from inner cortical cells (Fig. 4K). Tetrasporangia decussately or cruciately divided, ovoid, $20\text{--}34 \times 19\text{--}24 \mu\text{m}$ in size (Fig. 4L, M).

Diagnosis. Diagnosed by a combination of characters: simple terete axes with irregular long branches and scarce short branchlets, hemispherical cystocarps with up to 3 ostioles, 9–14 cell-layered pericarp, and DNA sequences (accession number: PV106182 for *rbcL* and PV106180 for *COI-5P*).

Type. INDONESIA • Bali, Nusa Lembongan Island, Tamarind Beach, $8^{\circ}40'47.51''\text{S}$, $115^{\circ}26'10.20''\text{E}$, 21 Jun. 2017, collected by Sung Min Boo without collection numbers (Holotype: PKNU00673!; Isotypes: PKNU00672!, PKNU00674!, and PKNU00676!; Paratype: PKNU00675!). Types are deposited in the herbarium of the Department of Marine Biology, Pukyong National University, Busan, Korea (PKNU).

Morphology and anatomy of *Gracilariaopsis grevogerungii* sp. nov. **A.** Surface view of axis showing irregularly arranged cortical cells; **B.** Longitudinal section of axis showing compact cortex and medulla; **C.** Transverse section of axis showing abrupt transition in cells size from cortex to medulla; **D.** Hemispherical cystocarp; **E.** Three ostioles on a single cystocarp; **F.** Longitudinal section of cystocarp showing early stage of gonimoblast; **G.** Longitudinal section of cystocarp lacking nutritive tubular cells between gonimoblast and pericarp; **H.** Two gonimoblasts sometimes formed within a single cystocarp; **I.** Longitudinal section of cystocarp showing releasing carpospores through ostiole; **J.** Tetrasporangia partially immersed by cortical cells; **K.** Tetrasporangial initial formed from inner cortical cells; **L, M.** Decussately to cruciately divided tetrasporangia. Scale bars: 20 µm (A, B, J–M); 100 µm (C, I); 400 µm (D); 200 µm (E); 40 µm (F–H).

Habitat and distribution. *Gracilariaopsis grevogerungii* grows on intertidal to shallow subtidal sandy-muddy substrates. It is currently demonstrated in the type locality solely using DNA sequences, but its range is likely expanded to the surrounding waters with additional collections (see Discussion).

Etymology. Species epithet is given in honor of Dr Grevo Soleman Gerung for his contributions to the knowledge of seaweed diversity in Indonesia.

Discussion

Gracilariopsis grevogerungii is the only described southern Indonesian species of *Gracilariopsis* investigated by both *rbcL* and COI-5P sequences, as well as morphology. The cystocarp anatomy revealed the chains of carposporangia and the lack of nutritive tubular cells, typical characters of *Gracilariopsis*. *Gracilariopsis grevogerungii* was likely misidentified as *Gp. lemaneiformis* based on specimens collected in Flores Island and Tanah Djampea, Indonesia (Weber-van Bosse 1928). Its illustration of cystocarp having 10–17 cell layers in pericarp and lacking the nutritive tubular cells matches well with *Gp. grevogerungii*.

Gracilariopsis grevogerungii has likely been misidentified as terete species of *Gracilaria*. For example, during the present study, *Gracilaria edulis* (S.G.Gmelin) P.C.Silva was collected in Benoa Bay, Bali, very close to Nasa Lembongan Island. It is a common species in Indonesia and also included in the export list of Indonesian hydrocolloid seaweeds (Meinita et al. 2021; Basyuni et al. 2024). However, COI-5P sequences from our collections of *G. edulis* (GHB, unpubl.) revealed its difference from *Gp. grevogerungii*. Again, *Gracilaria* is well segregated from *Gracilariopsis* by the presence of nutritive filaments in the cystocarp and by molecular data (Gurgel et al. 2003b; Bellorin et al. 2008).

Gracilariopsis sp. from Zamboanga city, Philippines, which lacks fine, determinate branchlets (Hurtado-Ponce and Liao 1998), is morphologically similar to *Gp. grevogerungii*. DNA sequences from the Philippine collection are necessary to confirm its identity. *Gracilariopsis lemaneiformis* has still been reported in China (Wang et al. 2023), even though it has been confirmed by *rbcL* sequences that the Chinese specimens do not correspond to *Gp. lemaneiformis* (whose type locality is in Peru), but to *Gp. chorda* (whose type locality is in Japan). Additional sampling at sand-muddy coastal regions will likely extend the range of *Gp. grevogerungii* into other locations in Indonesia or surrounding waters.

Two species of *Gracilariopsis* were closely related to *Gp. grevogerungii* in both *rbcL* and COI-5P phylogenies. *Gracilariopsis mclachlanii*, originally described for Tanzanian specimens, is recognized by large cylindrical form of thallus, 8–13 cell layers of pericarp, and cleavage of spermatangia from spermatangial mother cells through concavo-convex oblique septa (Bellorin et al. 2008). *Gracilariopsis heteroclada*, first described for Chinese specimens, is characterized by slender, filiform indeterminate branches that arise alternatively and are beset with fine, regularly-disposed determinate branchlets (Zhang and Xia 1988; Hurtado-Ponce and Liao 1998).

Several species of *Gracilariopsis*, including *Gp. heteroclada*, have been previously recognized in Southeast Asia (Pham 1969; Le and Lin 2006; Lin 2008; Muangmai et al. 2014). Most species except foliose *Gp. mageshimensis* Mas. Suzuki & R.Terada from Japan resemble *Gp. grevogerungii* in their habits with filiform thalli having irregular lateral branches from main axes (Table 2). Of these, *Gp. chiangii* Showe M.Lin, *Gp. heteroclada*, and *Gp. nhatrangensis* Nhu Hau Le & Showe M.Lin have been well delimited by DNA sequences and morphology (Le and Lin 2006; Lin 2008; Wang et al. 2023). *Gracilariopsis chiangii* is characterized by small-sized thallus (15–22 cm in length) and 1–2(–3) orders of branches from the base to middle part of thallus (Lin 2008). *Gracilariopsis nhatrangensis* is characterized by 1–15 main branches (up to 18 cm tall), arising from a discoid holdfast and numerous, racemose branchlets on main axes (Le and Lin 2006).

Gracilariopsis irregularis from Thailand is distinguished by having short (up to 10 cm) and succulent axes with an irregular secondary branching pattern (Muangmai et al. 2014). However, *Gp. irregularis* requires reexamination by COI-5P and other molecular markers because of its homogeneity to *Gp. heteroclada* in *rbcL*. It is important to reexamine the holotypes or topotype materials of two Vietnamese species, *Gp. nganii* Pham and *Gp. phanthiens* Pham, which have not been recorded since the original publication (Le and Lin 2006; Pham 1969), to elucidate their relationships with *Gp. grevogerungii* and other *Gracilariopsis* species. Because most *Gracilariopsis* species have similar vegetative traits (Bellorin et al. 2008), it is difficult to discriminate *Gp. grevogerungii* from other cylindrical species of *Gracilariopsis* in Southeast Asia without DNA sequences.

Conclusions

DNA sequence analyses were essential for the recognition of a new tropical species, *Gracilariopsis grevogerungii*, from southern Indonesia. This study highlights the critical role of molecular data in elucidating the biodiversity of a morphologically simple group of marine red algae. *Gracilariopsis grevogerungii*, along with *Gracilaria* species, is expected to be included in the export list of Indonesian hydrocolloid seaweeds. Our integrative taxonomy, combining molecular and morphological evidence, contributes to the clarification of commercial seaweed species and the cataloguing of red algal biodiversity. This study emphasizes the necessity for continued taxonomic and molecular investigations of the agar-producing genus *Gracilariopsis* in Indonesia and adjacent regions.
